LE TRAITEMENT ENDOSCOPIQUE DU REFLUX GASTRO-OESOPHAGIEN

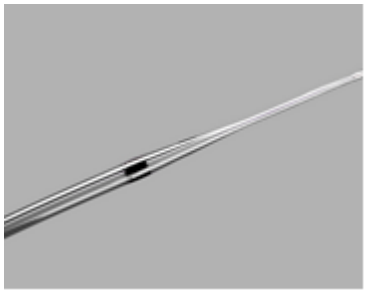
Héla ELLOUMI
Hôpital Habib Thameur

Club Endoscopie- 27 avril 2019- Hammamet

- Traitement du RGO compliqué
  (sténose, anneau de Schatzki, EBO)

- Traitement du RGO non compliqué

DILATATION- STÉNOSE PEPTIQUE



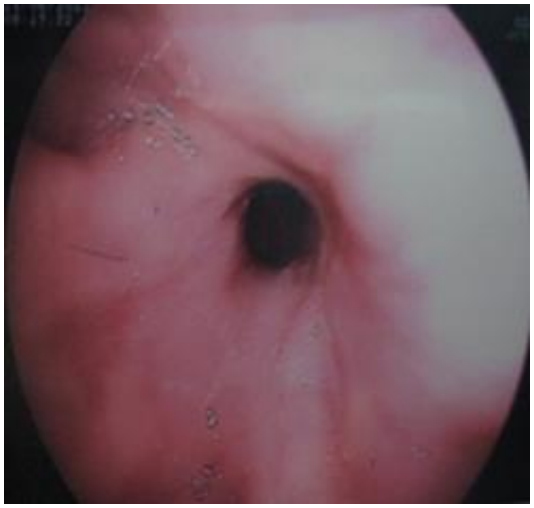
∅ 5-20mm

Bougies de
Savary-Gilliard
en polyvinyl

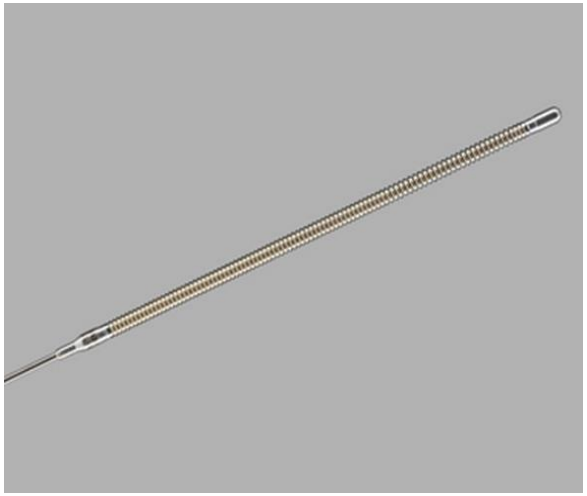
Ballonnet hydrostatique
type CRE Wireguided
(Boston*)
en polyéthylène

∅: 4-20 mm-
L : 5- 8 cm
P: 3-8 ATM

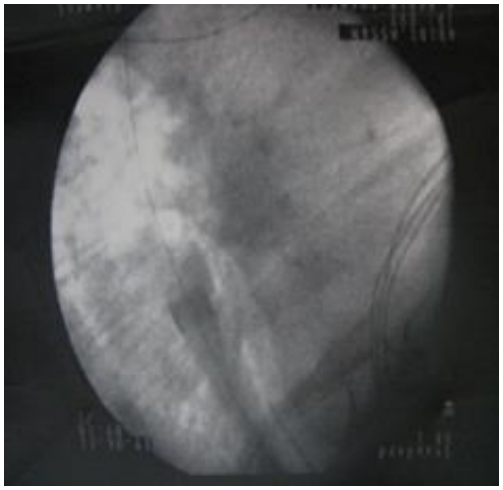
Dilatation- Bougies de Savary-Gilliard



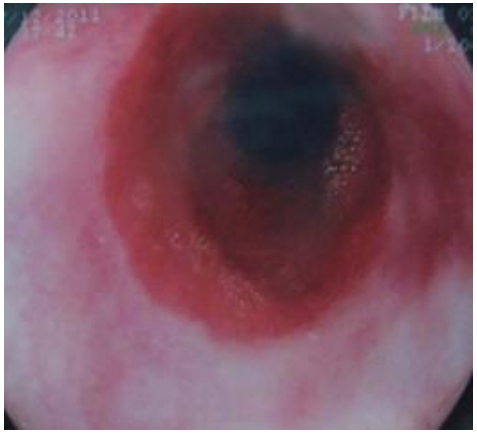
Caractérisation de la sténose



Fil guide métallique de savary

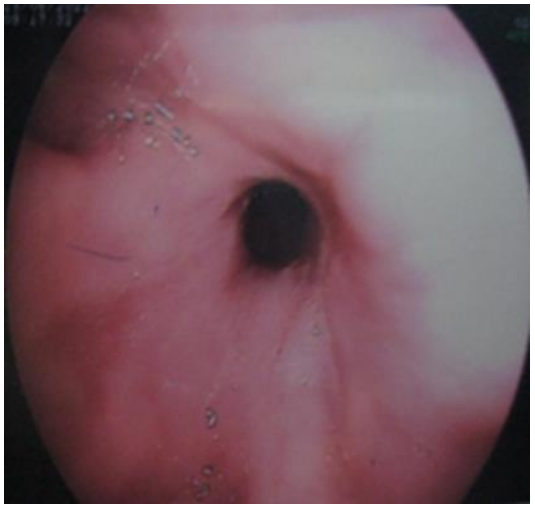


Contrôle sous scopie

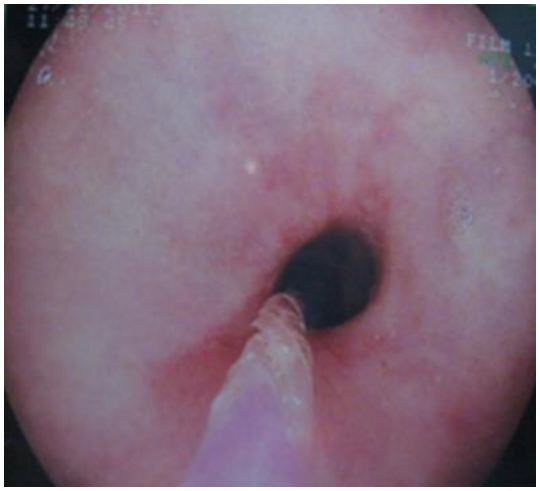


Contrôle en fin de procédure: Saignement

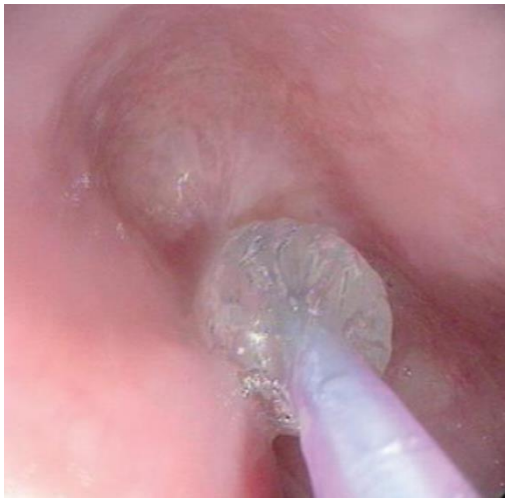
Dilatation hydrostatique



La sténose

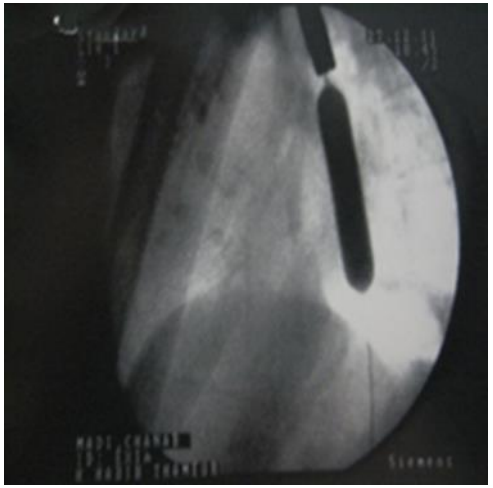


Ballonnet TTS

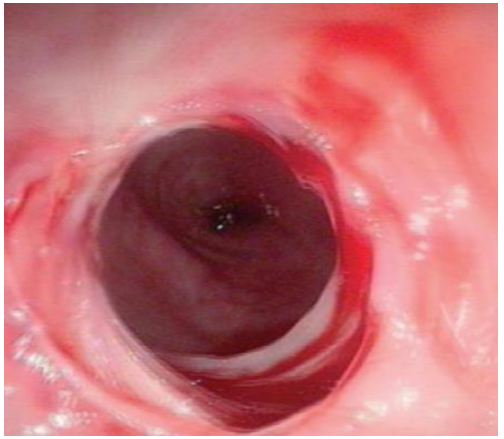


Partie médiane du ballonnet
à cheval sur la sténose

Dilatation progressive



Contrôle scopique



Contrôle endoscopique
Fin de procédure

Bougie versus ballon

- IPP +++
- Perforation : 0,4 à 1 %- **[Règle de 3/session]**
- pas de différence d'efficacité ou de complication
- Efficacité moyenne après 3 séances de dilatation > 80%
- Sténose réfractaire : nécessité au max 5 séances/2sem
- Injection de stéroïdes
- Deux études randomisées (stéroïde +dilat) vs dilat seule
  - *Ramage*: nouvelles dilatations 13 % vs 60 %
  - *Dunne: diminution du nombre de dilatation 6 à 2*

TRAITEMENT DU RGO NON COMPLIQUÉ

- Progrès ces 20 dernières années
- Développement technologique de la chirurgie laparoscopique
- Alternative au traitement chirurgical

-Réalisation plus simple

-Moins invasives

-Moins d'effets secondaires

-Réalisation en ambulatoire

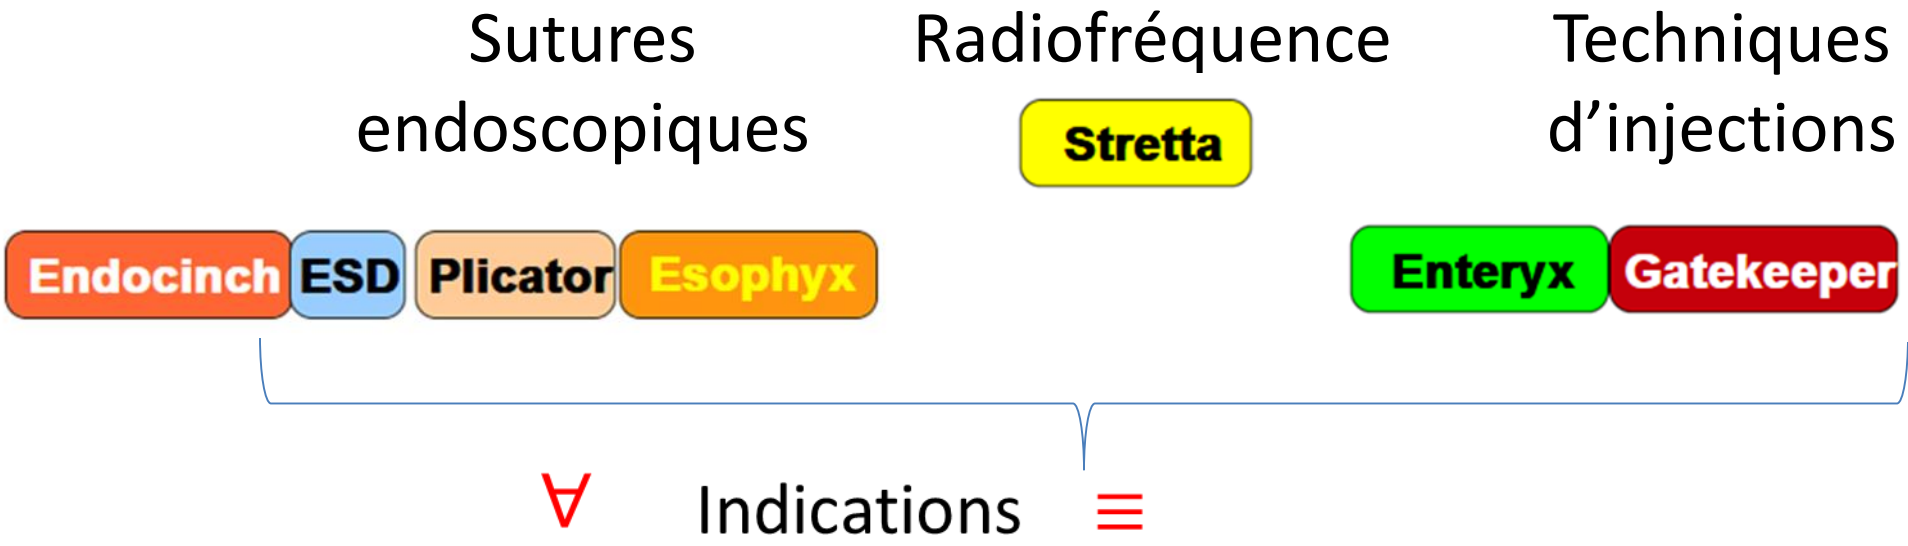
-Possibilité de répéter le traitement

-Potentiellement réversible

Moyens

- ~ 10 méthodes en évaluation clinique ou au stade expérimental

- Classées en 3 catégories



Indications

- Dépendance aux IPP

Sans HH > 2 cm

Sans muqueuse de Barrett

Sans œsophagite sévère

Arrêter la prise des IPP

Rétablir une
barrière anti-reflux

Modifier
la fonction ou
l'anatomie de la JOG

LA RADIOFREQUENCE

Hyperthermie par radiofréquence

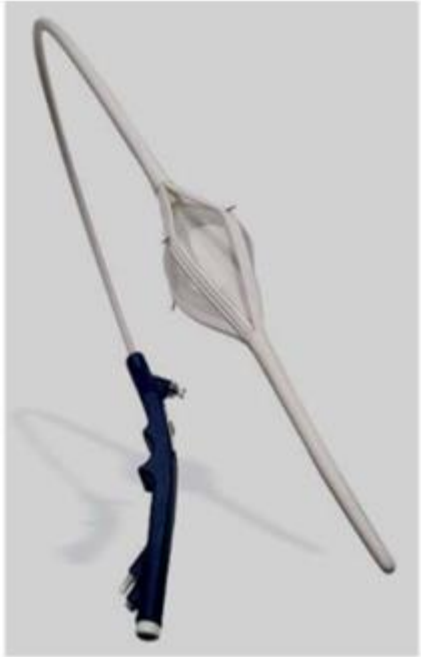
- Principe: Induire des lésions thermiques du SIO et du cardia proximal

- Conséquence: Epaississement pariétal par fibrose extensive de la paroi et une destruction des canaux nerveux à l'origine des relaxations transitoires du SIO

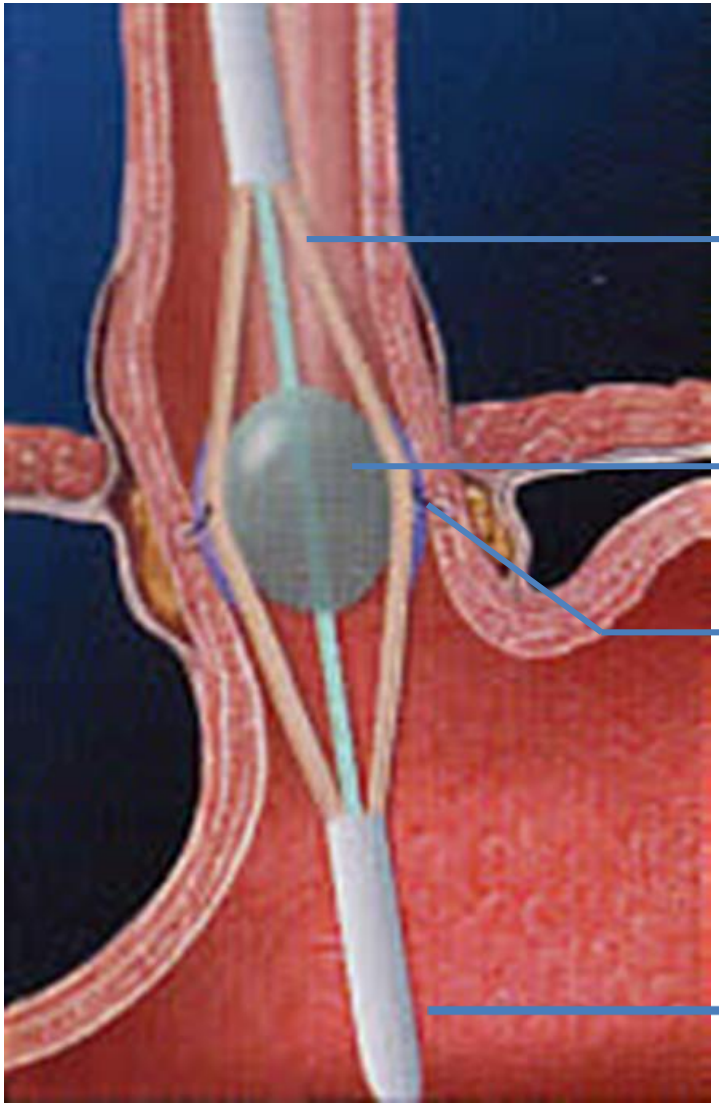
Radiofréquence

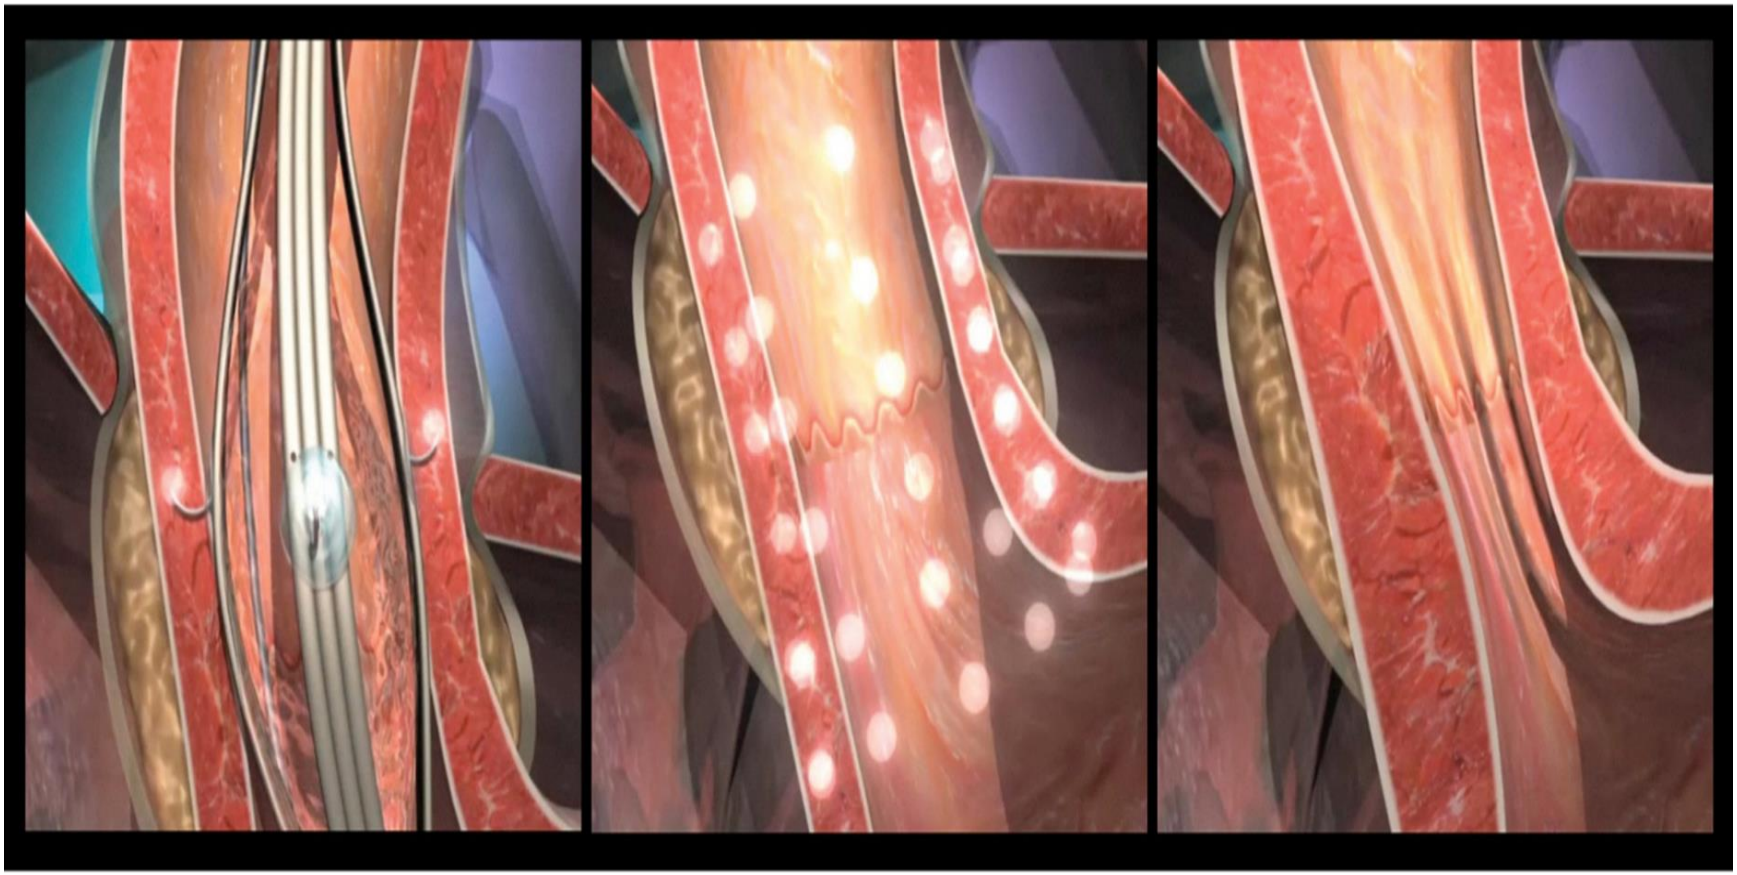
Stretta

CURON STRETTA Sunnyvale, CA USA

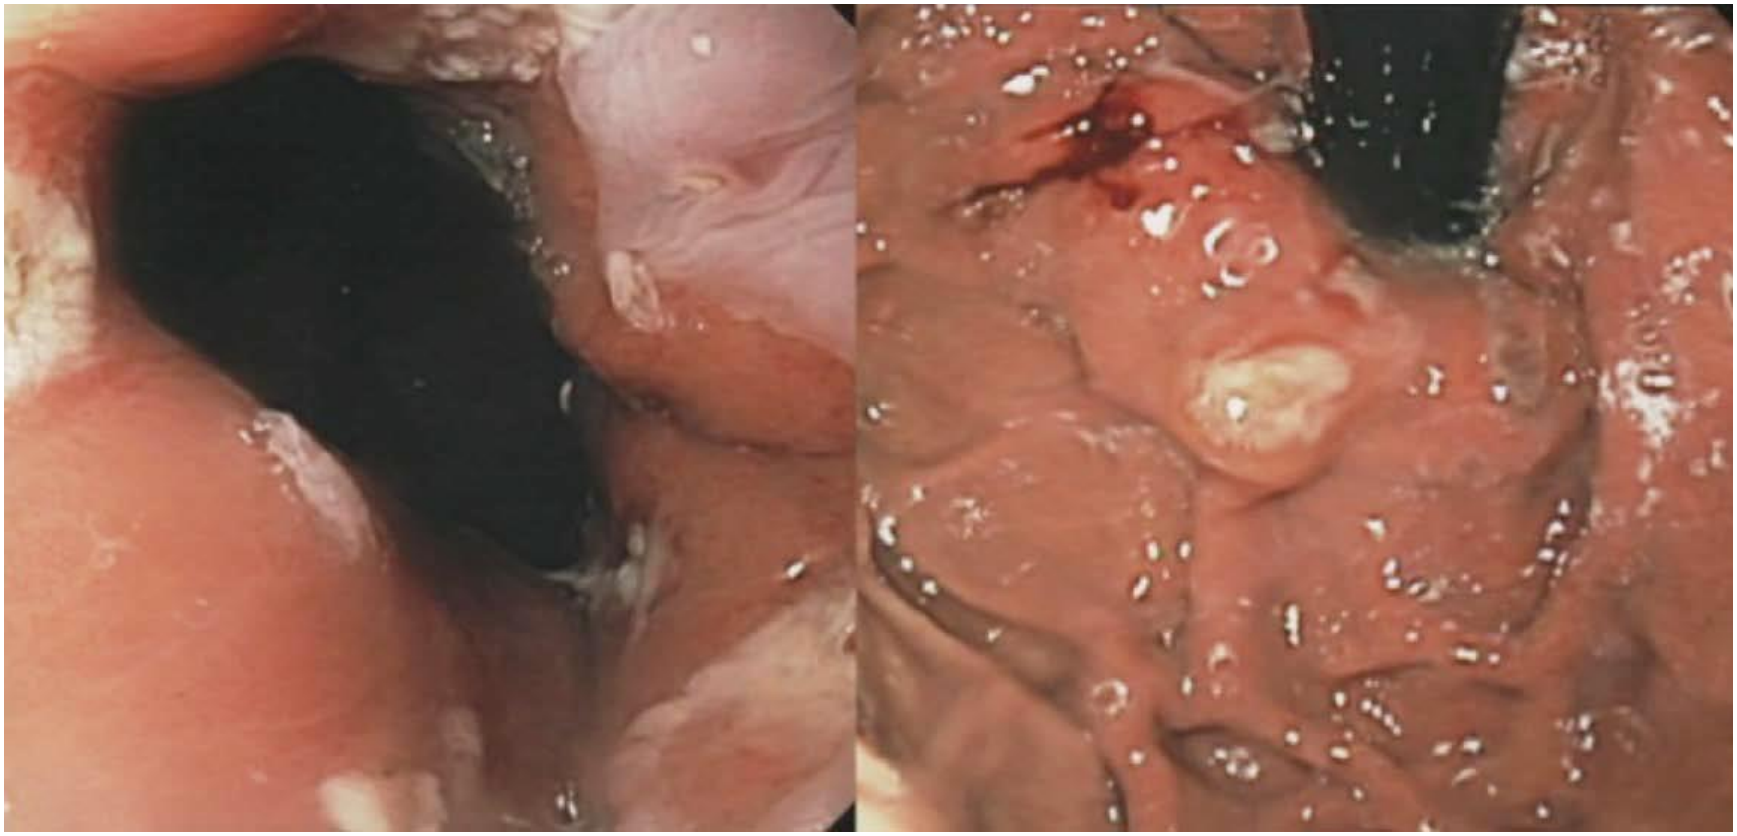


Stretta





série répétée tous les 0,5 cm vers l'intérieur, couvrant une zone de 2 cm au-dessus et à 0,5 cm en dessous de la jonction squamo-colonnaire.



World J Gastroenterol 2014; 20: 7730-8

Indications de Stretta:

- une œsophagite grade A ou B
- PHmétrie anormale: score de DeMeester ≥14,7 avec corrélation des symptômes ≥ 50% et / ou épisodes de reflux> 73 sur 24 heures;
- Absence de HH ou HH < 2 cm
- Absence d'œsophage de Barrett
- Absence de pression très basse du SIO (<5mmHg)

REVIEW

Systematic review and meta-analysis of controlled and prospective cohort efficacy studies of endoscopic radiofrequency for treatment of gastroesophageal reflux disease

Ronnie Fass[1] · Frederick Cahn[2] · Dennis J. Scotti[3] · David A. Gregory[4]

Received: 9 October 2016 / Accepted: 20 January 2017 / Published online: 23 February 2017

Abstract

Background The endoscopic radiofrequency procedure (Stretta) has been used for more than a decade to treat patients with gastroesophageal reflux disease (GERD). However, the efficacy of the procedure in improving objective and subjective clinical endpoints needs to be further established

36.7] months. The pooled results showed that the Stretta reduced (improved) the health-related quality of life score by −14.6 [−16.48, −12.73] ($P<0.001$). Stretta also reduced (improved) the pooled heartburn standardized score by −1.53 [−1.97, −1.09] ($P<0.001$). After Stretta treatment, only 49% of the patients using proton pump inhibitors (PPIs) at baseline required PPIs at follow-up

Méta-analyse 2017

- But: Déterminer l'efficacité de Stretta
- 28 études, 2468 patients
- Essais contrôlés randomisés (n=4)
- Cohortes prospectives (n=23)
- Registre prospectif (n=1)

Fass R. Surg Endos (2017): 31; 4865-82

Critères de jugement

- Questionnaire Qualité de vie
- Score de pyrosis
- Utilisation des IPP
- Œsophagite érosive
- Exposition acide de l'œsophage
- Pression basale du SIO

Fass R. Surg Endos (2017): 31; 4865-82

Radiofrequency energy delivery to the lower esophageal sphincter improves gastroesophageal reflux patient-reported outcomes in failed laparoscopic Nissen fundoplication cohort

Mark Noar[1] · Patrick Squires[2] · Sulman Khan[3]

Received: 8 July 2016 / Accepted: 14 October 2016 / Published online: 30 December 2016

Abstract

Background Patients with uncontrollable gastroesophageal reflux disease (GERD) often undergo laparoscopic Nissen fundoplication (LNF); however, long-term there are often recurring symptoms and need for continuous medication use. Refractory LNF patients may receive radiofrequency energy delivery to the lower esophageal sphincter (Stretta) to ameliorate symptoms and medication requirements. The aim was to assess and compare long-term patient-reported outcomes of Stretta in refractory patients with and without previous LNF.

Methods We prospectively assessed and compared patient-reported outcomes in 18 refractory LNF patients and 81 standard refractory GERD patients that all underwent Stretta during 10-year follow-up. Patient-reported outcomes measured were GERD-HRQL (health-related quality of life), patient satisfaction scores, and daily medication requirements.

Results The refractory LNF subset demonstrated median improvements in GERD-HRQL, satisfaction, and medication use at all follow-up time points ≥6 months to 10 years, which was significant from a baseline of both on- and off-medications ($p < 0.05$). Specifically at 10 years, median GERD-HRQL decreased from 36 to 7 ($p < 0.001$), satisfaction increased from 1 to 4 ($p < 0.001$), and medication score decreased from 7 to 6 ($p = 0.040$). Nine patients decreased medication use by half at 10 years. No significant differences existed between refractory LNF and standard refractory GERD subsets at any follow-up time point ≥6 months to 10 years ($p > 0.05$) after Stretta. At 10 years, no significant differences were noted between refractory LNF and standard Stretta subsets regarding medication use ($p = 0.088$), patient satisfaction ($p = 0.573$), and GERD-HRQL ($p = 0.075$). Stretta procedures were completed without difficulty or significant intraoperative or long-term adverse events.

Conclusion Within a small cohort of refractory LNF patients, Stretta resulted in sustained improvement over 10 years with equivalent outcomes to non-LNF standard Stretta patients. Refractory LNF patients are a subpopulation that may be safely, effectively, and robustly aided by Stretta with fewer complications compared to redo of Nissen or chronic medication use.

Chirurgie vs Endoscopie ?

Endoscopic and laparoscopic treatment of gastroesophageal reflux.

Abstract

Gastroesophageal reflux is extremely common in Western countries. For selected patients, there is an established role for the surgical treatment of reflux, and possibly an emerging role for endoscopic antireflux procedures. Randomized trials have compared medical versus surgical management, laparoscopic versus open surgery and partial versus total fundoplications. However, the evidence base for endoscopic procedures is limited to some small sham-controlled studies, and cohort studies with short-term follow-up. Laparoscopic fundoplication has been shown to be an effective antireflux operation. It facilitates quicker convalescence and is associated with fewer complications, but has a similar longer term outcome compared with ope antireflux surgery. In most randomized trials, antireflux surgery achieves at least as good control of reflux as medical therapy, and these studies support a wider application of surgery for the treatment of moderate-to-severe reflux. Laparoscopic partial fundoplication is an effective surgical procedure with fewer side effects, and it may achieve high rates of patient satisfaction at late follow-up. Many of the early endoscopic antireflux procedures have failed to achieve effective reflux control, and they have been withdrawn from the market. Newer procedures have the potential to fashion a surgical fundoplication. However, at prese there is insufficient evidence to establish the safety and efficacy of endoscopic procedures for the treatment of gastroesophageal reflux, and no endoscopic procedure has achieved equivalent reflux control to that achieved by surgical fundoplication.

ABSTRACT – **Background** – Endoscopic antireflux treatments for gastroesophageal reflux disease (GERD) are still evolving, and most of the published studies address symptom relief in the short-term. **Objective** – We aimed to perform a systematic review and meta-analysis focused on evaluating the efficacy of the different endoscopic procedures. **Methods** – Search was restricted to randomized controlled trials (RCTs) on MedLine, Cochrane, SciELO, and EMBASE for patients with chronic GERD (>6 months), over 18 years old and available follow up of at least 3 months. The main outcome was to evaluate the efficacy of the different endoscopic treatments compared to sham, pharmacological or surgical treatment. Efficacy was measured by different subjective and objective outcomes. **Results** – We analyzed data from 16 RCT, totaling 1085 patients. The efficacy of endoscopic treatments compared to sham and proton pump inhibitors (PPIs) treatment showed a significant difference up to 6 months in favor of endoscopy with no heterogeneity ($P<0.00001$) (I^2: 0%). The subgroup analysis showed a statistically significant difference up to 6 months in favor of endoscopy: endoscopy vs PPI ($P<0.00001$) (I^2: 39%). Endoscopy vs sham ($P<0.00001$) (I^2: 0%). Most subjective and objective outcomes were statistically significant in favor of endoscopy up to 6 and 12 months follow up. **Conclusion** – This systematic review and meta-analysis shows a good short-term efficacy in favor of endoscopic procedures when comparing them to a sham and pharmacological or surgical treatment. Data on long-term follow up is lacking and this should be explored in future studies.

FDA Preliminary Public Health Notification*: Recall of Boston Scientific ENTERYX® Procedure Kits and ENTERYX® Injector Single Packs for Treatment of Gastroesophageal Reflux Disease (GERD)

October 14, 2005

Dear Health care practitioner:

This is to let you know about serious adverse events, including death, occurring in patients treated with Boston Scientific's ENTERYX® for gastroesophageal reflux disease (GERD), and to provide recommendations on avoiding future occurrences.

On September 23, 2005, Boston Scientific Corporation issued a recall of ALL ENTERYX® Procedure Kits and ENTERYX® Injector Single Packs from commercial distribution. ***Physicians should stop injecting ENTERYX® immediately and follow the manufacturer's procedures for returning unused product.***

Abstract

BACKGROUND: This study aimed to assess whether endoscopic implantation of an injectable esophageal prosthesis, the Gatekeeper Reflux Repair System (GK), is a safe and effective therapy for controlling gastroesophageal reflux disease (GERD). METHODS: A prospective, randomized, sham-controlled, single-blinded, international multicenter study planned final enrollment of 204 patients in three groups: up to 60 lead-in, 96 GK, and 48 sham patients. The sham patients were allowed to cross over to the GK treatment arm or exit the study at 6 months. The primary end points were (1) reduction in serious device- and procedure-related adverse device effects compared with a surgical composite complication rate and (2) reduction in heartburn symptoms 6 months after the GK procedure compared with the sham procedure. The secondary end point was improved esophageal pH (total time pH was <4) 6 months after the GK procedure compared with baseline. RESULTS: A planned interim analysis was performed after 143 patients were enrolled (25 lead-in, 75 GK, and 43 sham patients), and the GK study was terminated early due to lack of compelling efficacy data. Four reported serious adverse events had occurred (2 perforations, 1 pulmonary infiltrate related to a perforation, and 1 severe chest pain) at termination of the study with no mortality or long-term sequelae. Heartburn symptoms had improved significantly at 6 months compared with baseline in the GK group ($p < 0.0001$) and the sham group ($p < 0.0001$), but no significant between-group difference in improvement was observed ($p = 0.146$). Esophageal acid exposure had improved significantly at 6 months compared with baseline in the GK group ($p = 0.021$) and the sham group ($p = 0.003$), but no significant between-group difference in improvement was observed ($p = 0.27$). CONCLUSIONS: The GK procedure was associated with some serious but infrequent complications. No statistically significant difference n outcomes was observed between the treatment and control groups at 6 months compared with baseline.

CONCLUSION
